

# DevOps Exercise Sheet 1

---

*Exercise - Containerize and run a pre-existing web page*

**Purpose:** The goal is to take a very small pre-existing web page, package it with Docker, run it locally, and understand the basic Docker workflow.

## Read this before you start

Use the official documentation first. Read enough to understand the concepts before you touch the exercise.

- [Docker Docs - Get started](#)
- [Docker Docs - What is Docker?](#)
- [Docker Docs - What is a container?](#)
- [Docker Docs - Images vs containers](#)
- [Docker Docs - Writing a Dockerfile](#)
- [Play with Docker - Getting Started](#)

## Concepts you should understand first

- What problem Docker solves
- What an image is
- What a container is
- What a Dockerfile is used for
- What it means to publish a port from the container to the host
- Why Docker helps avoid "it works on my machine" situations

## Exercise brief

**Scenario:** You have been given a web page. Your job is to make it run inside a container and expose it locally so it can be opened in a browser.

## What you need to achieve

- Take the provided web page and place it in a small project folder.
- Understand how to expose the web page locally.
- Build a Docker image locally.
- Run the container on your machine.
- Expose the service so the page can be reached from a browser on localhost.

## Expected outcome

- The page is exposed in localhost and can be reached through the browser.
- The container is running successfully.
- Another person could use your project files to get the same result.
